Reliability and Validity

Reliability

Reliability refers to a test's stability, consistency, and accuracy. When used to measure a stable construct, scores that are highly reliable will yield consistent, accurate results across factors such as time and examiner. The following section considers several indicators of reliability, including internal consistency, standard error of measurement, stability of test scores over time, as well as inter-scorer consistency on the subjective scoring of AAB subtests.

Internal Consistency

Coefficient alpha is a commonly used measure of internal consistency when there are multiple items within a subtest or composite assessing the same construct. The most widely used statistic for estimating this is Cronbach's (1951) alpha. An overview of the internal consistency reliability coefficients for each AAB subtest and composite for the age- and grade-based normative samples can be found in Table 5.1. As shown in Table 5.1, these range from .77 to .98, indicating an overall high level of internal consistency. In addition, the internal consistencies for the AAB subtests and composites are also reported for each of the normative age and grade groups (see Tables 5.2 through 5.9).

Standard Error of Measurement

Standard error of measurement (*SEM*) is an alternate measure of reliability. The formula for the *SEM* is based on the coefficient alpha (see Tables 5.2 through 5.9) and the standard deviation for each subtest (in standard units). When multiplied by a critical value and banded around an individual's score, the *SEM* provides a range of scores into which an individual's true score is likely to fall. For more information about the development of confidence intervals, see Chapter 3 of this Professional Manual. The *SEMs* for the AAB are presented in Tables 5.10 through 5.13. Confidence intervals based on the *SEMs* can be found in Appendixes B, C, and D for the age- and grade-based normative samples.

Test-Retest Reliability

Test score stability refers to the extent to which an individual's test performance remains constant over time. The stability of the AAB subtest and composite scores over time was evaluated by retesting a subset of individuals from the standardization sample. Demographic characteristics of the test-retest sample are presented in Table 5.14. The interval between the two test administrations ranged from 7 to 49 days, with a median test-retest interval of 18 days. The correlations between Time 1 scores and Time 2 scores are provided in Table 5.15. The test-retest coefficients range from .74 to .95 for the subtests and from .79 to .95 for the composites, which indicates a high degree of temporal stability.

Inter-Scorer Reliability

Inter-scorer reliability refers to the amount of error attributed to examiner variability in the scoring of the test. To measure inter-scorer reliability, two trained individuals scored a set of tests independently. The correlation between those independent sets of test scores indicates the degree of agreement between the scorers. Only the Pre-Writing Skills and Written Composition subtests were included in this type of analysis because their scoring is subjective.

Pre-Writing Skills

To assess the inter-scorer reliability of the Pre-Writing Skills subtest, 20 randomly selected protocols were scored independently by two trained research assistants. The scores were never discrepant by more than 1 point on any figure. Furthermore, the average difference between the total raw scores assigned by each scorer was only 1.6 points, with the total raw scores being the same or within 1 point of each other 55% of the time. In addition, intraclass correlation coefficients (ICCs) were calculated for the Pre-Writing Skills subtest using a two-way random effects model (consistency type). The ICCs ranged from .64 to .96 across the seven Pre-Writing Skills items (see Table 5.16). The ICC was also calculated for the Pre-Writing Skills total score and found to be high (.89).

Table 5.1
Reliability Coefficients of AAB Subtests and Composites by Age and Grade

Subtest/composite	Age-based sample	Grade-based sample	
		Fall	Spring
Reading Foundational Skills	.95	.95	.94
Letter/Word Reading	.94	.97	.97
Reading Fluency	.94	.91	.91
Basic Reading	.96	.98	.98
Reading Comprehension: Words and Sentences	.90	.96	.95
Reading Comprehension: Passages	.88	.81	.81
Reading Comprehension	.94	.96	.96
Listening Comprehension: Words and Sentences	.77	.88	.87
Listening Comprehension: Passages	.81	.78	.78
Listening Comprehension	.81	.84	.86
Oral Fluency	.80	.79	.79
Oral Expression	.84	.91	.92
Oral Production	.83	.80	.80
Expressive Communication	.88	.90	.91
Pre-Writing Skills	.92	.90	.91
Spelling	.94	.97	.97
Written Composition	.89	.93	.93
Written Expression	.95	.95	.96
Mathematical Calculation	.92	.93	.92
Mathematical Reasoning	.95	.95	.96
Academic Achievement Battery	.92	.94	.94

Note. Test-retest correlations were used for Reading Fluency, Reading Comprehension: Passages, Listening Comprehension: Passages, Oral Fluency, and Oral Production subtests. Correlations for these subtests were corrected for attenuation (Thorndike, 1949). All other subtests used the internal consistency. Those correlations were corrected for the variability of the standardization sample (Allen & Yen, 1979; Magnusson, 1967).

Table 5.2
Reliability Coefficients of AAB Subtests for Individuals Ages 4 to 18 Years

Subtest	Age (years)															Overall average r_{xx}^a

Academic Achievement Battery	.94	.94	.94	.94	.91	.94	.94	.94	.94	.94	.94	.94	.94	.94	.94

Note. The reliabilities for the indexes were calculated with the formula recommended by Guilford (1954) and Nunnally (1978).

^aAverage reliability coefficients were calculated with Fisher's z transformation (Fisher, 1915, 1921).

Written Composition

To assess the inter-scorer reliability of the Written Composition subtest, 20 randomly selected protocols were scored independently by two trained research assistants. The average difference between the total raw scores assigned by each scorer was only 1.5 points, with the totals being the same or within 1 point of each other 60% of the time. In addition, across the seven criteria that make up the Written Composition subtest, the ICCs ranged from .78 to .95 (see Table 5.17). An ICC was also calculated for the Written Composition subtest total score and found to be high (.97).

Validity

A valid test is one that accurately measures the psychological construct for which it is intended. Test validity is multidimensional in nature and should be evaluated using a variety of different sources and methodologies, each providing unique evidence that supports the validity of the test. In the following sections, intercorrelations between AAB subtests and composites as well as content,

construct, and criterion validity are considered together as evidence of the AAB's validity.

Intercorrelations

Intercorrelations between subtests and composite scores for the age- and grade-based samples can be found in Appendix N of this Professional Manual.

Content Validity

Content validity is the extent to which items included on a test represent the domain being assessed (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 2014; Anastasi & Urbina, 1997). While the AAB items were developed, a thorough review of the academic standards related to each construct area was conducted and used as a guide. More information regarding AAB content development can be found in Chapter 4 of this Professional Manual. For an overview of item characteristics, see Appendix I of this Professional Manual.

During the development of the AAB, multiple rounds of item review were conducted to ensure that the resulting

Table 5.10
Standard Errors of Measurement for AAB Subtests and Composites for Individuals Ages 4 to 18 Years

Subtest/composite	Age (years)															Mean

12 years	30.6
13-15 years	31.3
16+ years	26.5

Note. Parent education level is used for individuals ages 4 to 21 years.

test represented the content it was designed to measure. As discussed in Chapter 4, the expert panel (a) reviewed items across all subtests to ensure that the content represented the intended constructs, (b) provided feedback on the face validity of the subtests and the quality of the items, and (c) advised on the appropriateness of the tasks across the age and grade range. This item evaluation process ensured that only items that best represented each construct were included in the final assessment.

Construct Validity

Construct validity is the extent to which a test measures the theoretical construct or trait it is designed to measure. The construct validity of the AAB was established by examining its relationship to other tests that measure both similar and dissimilar constructs. The expectation was that the AAB would correlate with other measures of similar constructs (e.g., reading comprehension), and these correlations would be higher than those obtained from measures of constructs less closely related to the content of the AAB (e.g., processing speed). Demographic information about the concurrent validity samples can be found in Table 5.18.

Note. All correlations are significant at the $p < .01$ level. Correlations were corrected for attenuation (Thorndike, 1949).

Correlations With Other Achievement Measures

Wechsler Individual Achievement Test, Third Edition. The Wechsler Individual Achievement Test, Third Edition (WIAT-III; Wechsler, 2009) is a comprehensive achievement test for individuals ages 4 to 50 years. It includes 15 subtests that make up seven composite measures of achievement: oral language, basic reading, total reading, reading comprehension and fluency, written expression, mathematics, and math fluency. Table 5.19 presents the correlations, means, and standard deviations between AAB scores and WIAT-III scores. Overall, the Academic Achievement Battery Composite shows a strong positive

correlation of .78 to WIAT-III Total Achievement score. As expected, similar subtests and composites showed moderate to strong positive correlations, including the correlations between the two basic reading composites ($r = .74$), the spelling subtests ($r = .88$), the word reading subtests ($r = .77$), the reading comprehension composites ($r = .77$), the math calculation/operations subtests ($r = .77$), and the mathematical reasoning/mathematical problem solving subtests ($r = .66$).

Kaufman Test of Educational Achievement, Second Edition. The Kaufman Test of Educational Achievement, Second

Note. WIAT-III = Wechsler Individual Achievement Test, Third Ed. (Wechsler, 2009). Sample size varies due to differing grade start points for each subtest. The Reading Foundational Skills, Pre-Writing Skills, and Alphabet Writing Fluency subtests included fewer than 10 participants; these data are excluded from this analysis.

* $p < .05$. ** $p < .01$.

Edition (KTEA-II; Kaufman & Kaufman, 2004) is a comprehensive achievement test for individuals ages 4 years, 6 months to 25 years. It includes 14 subtests that make up eight composite measures of achievement: reading, math, written language, oral language, sound-symbol, oral fluency, decoding, and reading fluency. Table 5.20 presents the correlations, means, and standard deviations between AAB scores and KTEA-II scores. Similar to the WIAT-III analysis, there is a strong positive correlation between the overall achievement score on the AAB and the KTEA-II Comprehensive Academic Composite ($r = .78$). In addition, correlations between similar subtests and composites are also high in the expected direction, including the correlations between the reading composites ($r = .73$), the mathematical reasoning composite/math concepts and applications subtest ($r = .78$), and the writing composites ($r = .85$).

Woodcock-Johnson Tests of Achievement, Third Edition. The Woodcock-Johnson Tests of Achievement, Third Edition (WJ-III; Woodcock, McGrew, & Mather, 2007) is a comprehensive achievement test for individuals ages 2 to 90+ years. The core test includes 13 subtests that address 13 clusters of achievement: broad reading, oral language, broad math, math calculation skills, broad written language, written expression, academic skills, academic fluency, academic applications, brief reading, brief math, brief writing, and brief achievement. Table 5.21 presents the correlations, means, and standard deviations between AAB scores and WJ-III scores. A strong positive correlation between the Academic Achievement Battery Composite and the WJ-III Total Achievement Cluster was found ($r = .80$). Moderate to strong correlations in the expected direction were also found among subtests and composites measuring related skills, including reading ($r = .70$), letter/word reading ($r = .67$), spelling ($r = .70$), math calculation ($r = .65$), and written language ($r = .70$).

Wide Range Achievement Test 4. The Wide Range Achievement Test 4 (WRAT4; Wilkinson & Robertson, 2006) is a screening achievement test for individuals ages 5 to 94 years. It includes four subtests (reading, sentence comprehension, spelling, and math computation) and one composite measure of reading. Table 5.22 presents the correlations, means, and standard deviations between AAB scores and WRAT4 scores. The AAB Basic Reading Composite and Reading Comprehension Composite both correlated strongly with the WRAT4 Reading Composite ($r = .80$ and $.72$, respectively). The AAB Word Reading subtest and the WRAT4 Reading subtest were found to have a strong correlation ($r = .86$). A similar pattern of correlations exists between the AAB Mathematical Calculation and Mathematical Reasoning composites and the WRAT4 Mathematical Computation subtest ($r = .75$ and $.54$, respectively). Finally, there is a

strong positive relationship between the two measures of spelling ($r = .85$).

Correlations With Intelligence Measures

Wechsler Intelligence Scale for Children, Fourth Edition. The Wechsler Intelligence Scale for Children, Fourth Edition (WISC-IV; Wechsler, 2003) is a comprehensive intelligence test for children ages 6 to 16 years. The core test includes 10 subtests that make up five composite measures of intelligence: verbal comprehension, perceptual reasoning, working memory, processing speed, and a total composite. Table 5.23 presents the correlations, means, and standard deviations between AAB scores and WISC-IV scores. The Full Scale Composite of the WISC-IV exhibited a strong positive correlation with the Academic Achievement Battery Composite ($r = .71$). The Verbal Comprehension Composite of the WISC-IV exhibited the strongest relationships with the AAB Basic Reading ($r = .50$), Listening Comprehension ($r = .57$), and Expressive Communication ($r = .56$) composites. Conversely, Processing Speed, a composite based on performance on a group of tasks most dissimilar to the content of the AAB, showed weak correlations throughout, the strongest of which was with the Expressive Communication ($r = .30$) and Mathematical Reasoning ($r = .28$) composites.

Wechsler Adult Intelligence Scale, Fourth Edition. The Wechsler Adult Intelligence Scale, Fourth Edition (WAIS-IV; Wechsler, 2008) is a comprehensive intelligence test for individuals ages 16 to 90 years. Similar to the WISC-IV, the WAIS-IV includes 10 subtests that make up six composite measures of intelligence: verbal comprehension, perceptual reasoning, working memory, processing speed, general ability, and a total composite. Table 5.24 presents the correlations, means, and standard deviations between AAB scores and WAIS-IV scores. Correlations exhibit a similar pattern to those found with the WISC-IV. There is a strong positive correlation between the two overall test scores ($r = .71$) as well as moderately strong relationships between the WAIS-IV Verbal Comprehension Composite and many AAB composites, with correlations ranging from $.45$ (Reading Comprehension) to $.53$ (Basic Reading, Listening Comprehension). Like the WISC-IV, there are weak relationships found between the Processing Speed Composite and the AAB composites, as they measure mostly dissimilar skills, with Expressive Communication again exhibiting the strongest relationship ($r = .38$).

Criterion Validity

Criterion validity can be defined as the extent to which a test can predict performance in real-life situations or distinguish individuals with different clinical attributes (American Educational Research Association,

Note. WRAT4 = Wide Range Achievement Test 4 (Wilkinson & Robertson, 2006). Sample size varies due to differing grade start points for each subtest. The Reading Foundational Skills and Pre-Writing Skills subtest analyses included fewer than 10 participants; these data are excluded from this analysis.

* $p < .05$. ** $p < .01$.

American Psychological Association, & National Council on Measurement in Education, 2014; Anastasi & Urbana, 1997). The AAB was administered to individuals in several different clinical groups, including individuals with specific learning disorder, intellectual developmental disorder, attention deficit/hyperactivity disorder (ADHD), and speech/language impairment. The performance of these groups was then compared to the performance of the AAB age-based sample of nonclinical individuals; the ability of the AAB to discriminate between these groups was analyzed. For each clinical group, the difference in mean performance was examined, and the effect size (Cohen's *d*; Cohen, 1988) is reported for each subtest and composite. Typically, a medium effect size ranges from .40 to .75, with large effects being greater than .75. Table 5.25 presents the demographic characteristics of the clinical samples.

Specific Learning Disorder

The AAB was administered to 68 individuals with a specific learning disorder. Table 5.26 presents the mean AAB subtest and composite scores for this group. The largest subtest discrepancy between the normative sample and the specific learning disorder sample was on the

Reading Fluency subtest. The performance of the specific learning disorder sample was analyzed to find how scores fell within the seven clinically relevant standard score ranges compared to the percentages predicted from the normal curve (see Table 5.27). As indicated, approximately 2.7% of the distribution would typically obtain a score less than or equal to a standard score of 69. On average, 32.4% of the specific learning disorder sample obtained a score in this range across all AAB subtest and composite scores. These results help illustrate the ability of the AAB to identify individuals with suspected specific learning disorders.

Intellectual Developmental Disorder

The AAB was administered to 63 individuals who had been identified as having an intellectual developmental disorder. Table 5.28 presents the mean AAB subtest and composite scores for this group. The range of discrepancies between the normative sample and the intellectual developmental disorder sample ranged from 22 to 50 standard score points. The performance of the intellectual developmental disorder sample was analyzed to find how scores fell within seven clinically relevant standard score ranges compared to the percent predicted

Academic Achievement Battery	48.3	19.5	15.6	11.9	4.7	0.0	0.0
<i>M</i>	32.4	17.8	16.2	25.3	6.3	1.5	0.6

Note. The Reading Foundational Skills and Pre-Writing Skills subtests were not administered to the learning disability group due to age.

from the normal curve (see Table 5.29). As mentioned earlier, approximately 2.7% of the normal distribution would typically obtain a score less than or equal to a standard score of 69. On average, 76.9% of the intellectual developmental disorder sample obtained scores at or below a standard score of 69 across all AAB subtests and composites.

Attention-Deficit/Hyperactivity Disorder

The AAB was administered to 62 individuals with a diagnosis of ADHD. Table 5.30 presents the mean AAB subtest and composite scores for this group. The range of score discrepancies between the ADHD sample and the normative sample was much smaller than those found in the specific learning disorder and intellectual developmental disorder analyses. The normal distribution provides a clearer picture (see Table 5.31). On average, 6.6% of the ADHD sample scored within the significantly below average range, compared to 2.7% predicted from the normal distribution. A similar comparison was

demonstrated in the percentage of the ADHD group that obtained scores in the moderately below average range. On average, 9.6% of the ADHD sample scored in this range, compared to 7.6% predicted from the normal distribution. For this group, it is also important to examine the specific subtests for which there are larger discrepancies between the two percentages. These findings are consistent with findings from other achievement measures administered to children and adults with ADHD.

Speech/Language Impairment

The AAB was administered to 33 students and adults with a diagnosis of speech/language impairment (SLI). Table 5.32 presents the mean AAB subtest and composite scores for this group. The score discrepancies between the SLI sample and the normative sample ranged from 1 to 19 standard score points. The largest discrepancies were found on the Written Composition, Reading Foundational Skills, Reading Fluency, and Oral Expression subtests. More than 24% of the SLI sample

scored within the significantly below average or moderately below average ranges across all AAB subtests and composites compared to 10.3% expected within these two performance ranges (see Table 5.33).

Summary

Establishing the validity of an assessment is an ongoing, dynamic process that begins with the initial design

and selection of content and continues throughout the development process and beyond. The data presented in this chapter provide strong evidence of several different aspects of test validity, including content, construct, and criterion validity. Evidence for the clinical utility, sensitivity, and overall validity of the AAB has also been presented. As with all tests, these data are only the beginning of the ongoing process of validation.
