

## Iowa Gambling Task™, Version 2

# Evaluate decision making: Now with a wider age range!

### At a Glance

**Purpose:** Evaluates decision making mediated by the prefrontal cortex

**Age:** 8-79 years

**Format:** Software

**Time:** 5-10 minutes

**Qualification Level:** C

The original IGT has been used in studies examining decision-making capacity with individuals diagnosed with a variety of conditions. The IGT2 features a **real-time gambling task** that resembles **real-world situations**. The task factors reward and punishment—the winning and losing of money—in such a way that it creates a conflict between immediate reward and delayed punishment, engaging the participant in a task to make advantageous choices. As in real life, the task offers choices that may be risky, but there is no obvious indication of how, when, or what to choose.

### The IGT2 is:

- **Administered on a computer.** The program generates a Score Report and T-score and raw score profiles as soon as the examinee has completed the task.
- **Customized to your needs.** Optional settings can be modified to your needs, including number of trials, intertrial intervals, type of currency, and starting amount of money.
- **Interpreted immediately.** Normative scores are produced automatically; you can compare the examinee's scores to those of a demographically corrected or U.S. Census-matched sample.

The IGT2 is a computerized assessment that assists in the evaluation of **decision making**. This revision reflects a **downward age extension to age 8 years**, allowing for use throughout the life span.

The IGT2 is ideal for assessing patients who exhibit poor decision-making skills in the presence of otherwise normal or unaffected intelligence because of head injury or insult or any other condition thought to impact the function of the prefrontal cortex.

Features a downward age extension to age 8 years that makes the IGT2 usable throughout the life span.

# The IGT2 can be used with individuals who have:

- Obsessive-compulsive disorder (OCD)
- Pathological gambling problems
- Psychosis
- Bipolar disorder
- ADHD
- Decision-making impairments
- Language impairments
- Memory deficits
- Brain damage
- Cognitive impairments
- Frontal lobe impairments
- Huntington’s disease
- Focal brain lesions
- Behavior disorders
- Substance abuse
- Chronic pain
