

# Behavior Rating Inventory of Executive Function<sup>®</sup>

## Teacher Form Interpretive Report

Generated by **PARiConnect**

by Peter K. Isquith, PhD, Gerard A. Gioia, PhD, and PAR Staff

Client name : Sample Client  
Client ID : 123  
Gender : Male  
Age : 8  
Test date : 05/01/2013  
Test form : Teacher Form  
Rater name : -Not Specified-  
Relationship to client: Teacher  
Class taught : -Not Specified-  
Has known student for : 6 months  
Knows student : Very Well

This report is intended for use by qualified professionals only and is not to be shared with the examinee or any other unqualified persons.

BRIEF<sup>®</sup>: Interpretive Report Copyright © 1996, 1998, 2000, 2001, 2002, 2003, 2004, 2007, 2008 by PAR. All rights reserved. May not be reproduced in whole or in part in any form or by any means without written permission of PAR.

Version: 3.10.041

The BRIEF was developed to provide a window into the everyday behavior associated with specific domains of the executive functions. The BRIEF can serve as a screening tool for possible executive dysfunction. The clinical information gathered from an in-depth profile analysis is best understood, however, within the context of a full assessment that includes (a) a detailed history of the child and the family, (b) performance-based testing, and (c) observations of the child's behavior. A thorough understanding of the BRIEF, including its development and its psychometric properties, is a prerequisite to interpretation. As with any clinical method or procedure, appropriate training and clinical supervision is necessary to ensure competent use of the BRIEF.

This report is confidential and intended for use by qualified professionals only. This report should not be released to the parents or teachers of the child being evaluated. If a summary of the results specifically written for parents and teachers is desired, the BRIEF Feedback Report can be generated and given to the interested parents and/or teachers.

*T* scores are used to interpret the child's level of executive functioning as reported by parents and/or teachers on the BRIEF rating forms. These scores are linear transformations of the raw scale scores ( $M = 50$ ,  $SD = 10$ ). *T* scores provide information about an individual's scores relative to the scores of respondents in the standardization sample. Percentiles, which are also presented within the BRIEF-SP, represent the percentage of children in the standardization sample who fall below a given raw score.

In the process of interpreting the BRIEF, review of individual items within each scale can yield useful information for understanding the specific nature of the child's elevated score on any given clinical scale. In addition, certain items may be particularly relevant to specific clinical groups. Placing too much interpretive significance on individual items, however, is not recommended due to lower reliability of individual items relative to the scales and indexes.

## Overview

Sample Client's teacher completed the Teacher form of the Behavior Rating Inventory of Executive Function (BRIEF) on 05/01/2013. There are no missing item responses in the protocol. Responses are reasonably consistent. The Negativity scale is elevated, suggesting either that the respondent's view of Sample Client may be excessively negative or that Sample Client may have significant executive dysfunction. In either case, the examiner should carefully review the BRIEF results in the context of other clinical information about the child and should question the validity of the BRIEF protocol. In the context of these validity considerations, ratings of Sample Client's executive function exhibited in everyday behavior reveal some areas of concern.

The overall index, the Global Executive Composite (GEC), was elevated (GEC  $T = 72$ , %ile = 96). Both the Behavioral Regulation (BRI) and the Metacognition (MI) Indexes were elevated (BRI  $T = 71$ , %ile = 94 and MI  $T = 71$ , %ile = 96).

Within these summary indicators, all of the individual scales are valid. One or more of the individual BRIEF scales were elevated, suggesting that Sample Client exhibits difficulty with some aspects of executive function. Concerns are noted with his ability to adjust to changes in routine or task demands (Shift  $T = 68$ , %ile = 94), modulate emotions (Emotional Control  $T = 77$ , %ile = 96), initiate problem solving or activity (Initiate  $T = 72$ , %ile = 97), plan and organize problem solving approaches (Plan/Organize  $T = 72$ , %ile = 96), organize his environment and materials (Organization of Materials  $T = 71$ , %ile = 96), and monitor his own behavior (Monitor  $T = 68$ , %ile = 93). Sample Client's ability to inhibit impulsive responses (Inhibit  $T = 64$ , %ile = 84) and sustain working memory (Working Memory  $T = 63$ , %ile = 88) is not described as problematic by the respondent.

Sample Client's scores on the Shift scale and the Emotional Control scale are significantly elevated compared to age- and gender-matched peers. This profile suggests significant problem-solving rigidity combined with emotional dysregulation. Children with this profile have a tendency to lose emotional control when their routines or perspectives are challenged and/or flexibility is required. In order to develop a

better understanding of Sample Client's difficulties, further examination of the situational demands that result in such a loss of emotional control would be helpful.

## BRIEF® Score Summary Table

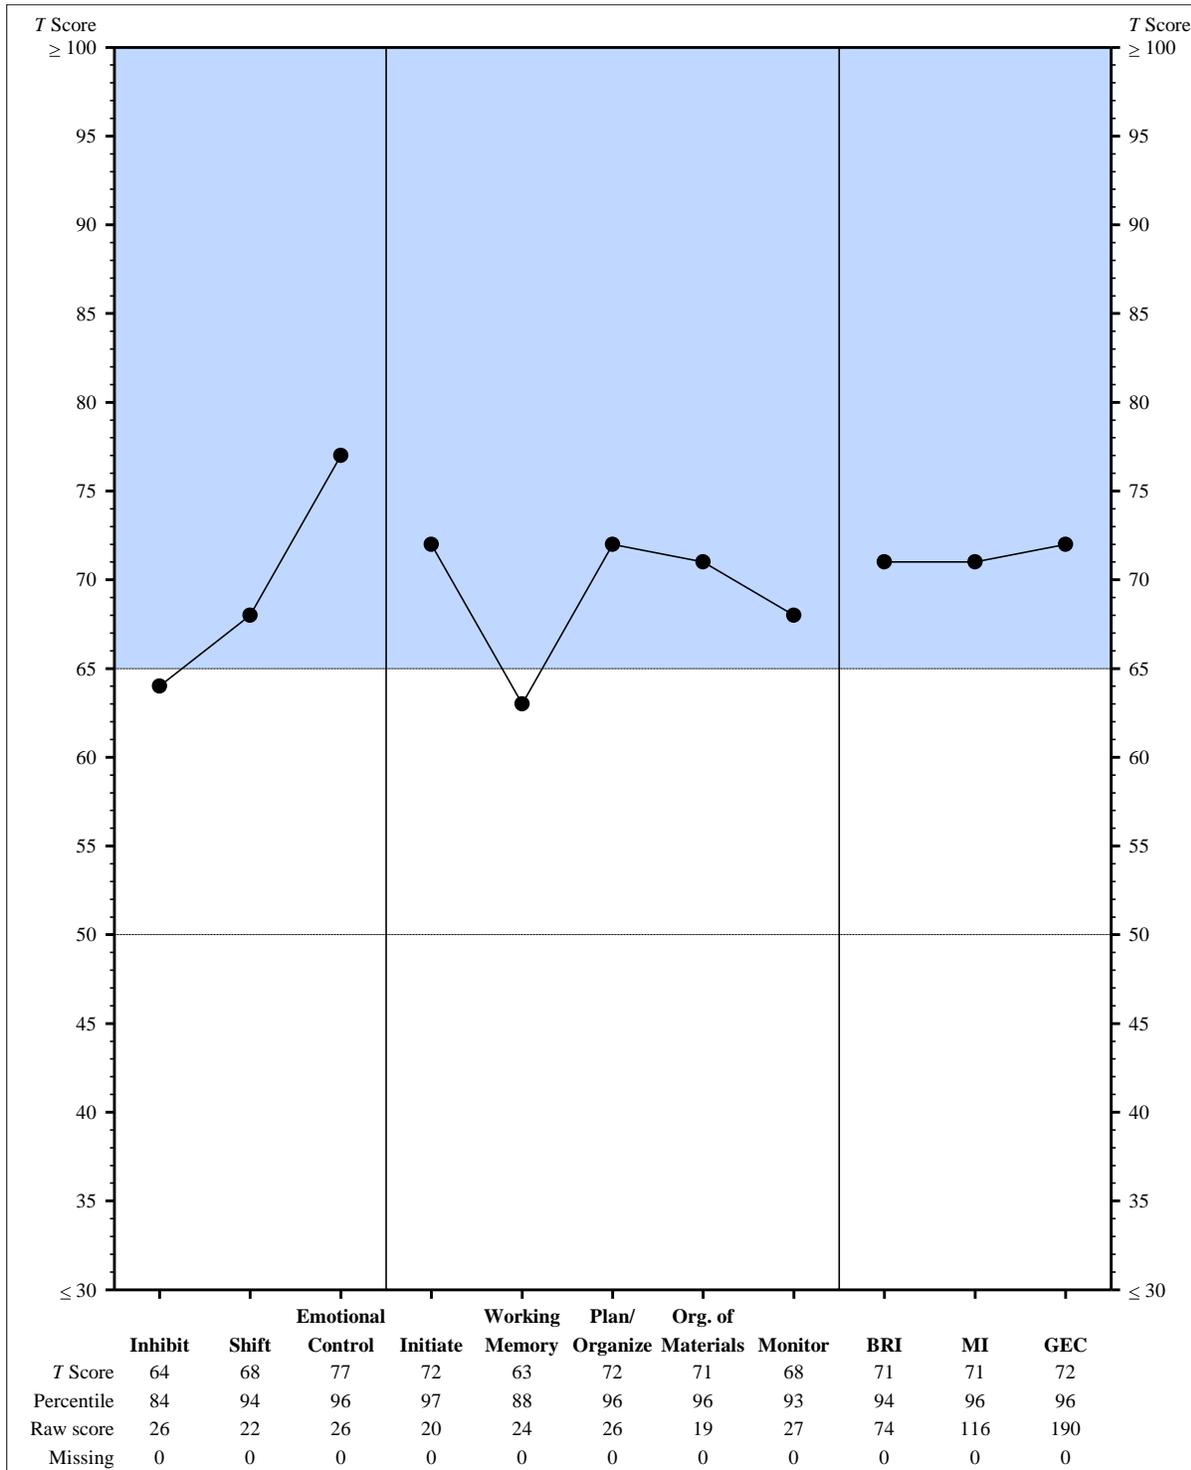

Index/scale	Raw score	T score	Percentile	90% C.I.
Inhibit	26	64	84	61 - 67
Shift	22	68	94	63 - 73
Emotional Control	26	77	96	73 - 81
Behavioral Regulation Index (BRI)	74	71	94	69 - 73
Initiate	20	72	97	67 - 77
Working Memory	24	63	88	59 - 67
Plan/Organize	26	72	96	67 - 77
Organization of Materials	19	71	96	67 - 75
Monitor	27	68	93	63 - 73
Metacognition Index (MI)	116	71	96	69 - 73
Global Executive Composite (GEC)	190	72	96	70 - 74

Validity scale	Raw score	Cumulative percentile	Protocol classification
Negativity	5	95 - 98	Elevated
Inconsistency	4	≤ 98	Acceptable

Note: Male, age-specific norms have been used to generate this profile.

For additional normative information, refer to Appendix A - D in the BRIEF® Professional Manual.

## Profile of BRIEF® T Scores

Note: Male, age-specific norms have been used to generate this profile.

For additional normative information, refer to Appendixes A - D in the BRIEF® Professional Manual.

## Validity

Before examining the BRIEF profile, it is essential to carefully consider the validity of the data provided. The inherent nature of rating scales (i.e., relying upon a third party for ratings of a child’s behavior) brings potential bias to the scores. The first step is to examine the protocol for missing data. With a valid number of responses, the Inconsistency and Negativity scales of the BRIEF provide additional validity indexes.

**Missing items**                      The respondent completed 86 of a possible 86 BRIEF items. For reference purposes, the summary table for each scale indicates the respondent’s actual rating for each item. There are no missing responses in the protocol, providing a complete data set for interpretation.

**Inconsistency**                      Scores on the Inconsistency scale indicate the extent to which the respondent answered similar BRIEF items in an inconsistent manner relative to the clinical samples. For example, a high Inconsistency score might be associated with marking Never in response to the item “Gets out of control more than friends” while at the same time marking Often in response to the item “Acts too wild or out of control.” Item pairs comprising the Inconsistency scale are shown in the summary table below. *T* scores are not generated for the Inconsistency scale. Instead, the raw difference scores for the 10 paired items are summed and the total difference score (i.e., the Inconsistency score) is used to classify the protocol as either “Acceptable,” “Questionable,” or as “Inconsistent.” The Inconsistency score of 4 falls within the Acceptable range, suggesting that the rater was reasonably consistent in responding to BRIEF items.

#	Content 1	Score 1	#	Content 2	Score 2	Diff
27	Mood changes frequently	3	26		2	1
36	<i>Remaining item content redacted for sample report</i>	3	39		2	1
42		2	43		3	1
45		3	9		2	1
46		3	65		3	0
47		3	58		3	0

## Negativity

The Negativity scale measures the extent to which the respondent answered selected BRIEF items in an unusually negative manner relative to the clinical sample. Items comprising the Negativity scale are shown in the summary table below. A higher raw score on this scale indicates a greater degree of negativity, with less than 3% of respondents scoring above 7 in the clinical sample. As with the Inconsistency scale, *T* scores are not generated for this scale. The Negativity score of 5 falls between the 95th and 98th percentiles and is elevated. This suggests that the respondent's view of Sample Client may be considerably negative and that the validity of the BRIEF protocol should be questioned. With an elevated Negativity scale, an unusually negative response style may have skewed the BRIEF results. It is also possible, however, that the BRIEF results represent accurate reporting on a child with severe executive dysfunction. An elevated Negativity scale score should prompt the examiner to carefully review the BRIEF results in the context of other information about the child, including BRIEF responses by other informants, other test performance, and the examiner's own observations of the child. Given that several items on the Shift scale are also included on the Negativity scale, the possibility of significant cognitive rigidity in the child should be considered. This may be an alternative explanation for a high Negativity score, particularly if the child has a diagnosis of Autistic Disorder/Pervasive Developmental Disorder (PDD) or another neurological disorder where inflexibility is a prominent symptom (e.g., severe traumatic brain injury).

## Composite and Summary Indexes

### **Global Executive Composite**

The Global Executive Composite (GEC) is an overarching summary score that incorporates all of the BRIEF clinical scales. Although review of the Metacognition Index, Behavioral Regulation Index, and individual scale scores is strongly recommended for all BRIEF profiles, the GEC can sometimes be useful as a summary measure. In this case, the two summary indexes are not substantially different, with *T* scores separated by 0 points. Thus, the GEC may capture the nature of the overall profile. With this in mind, Sample Client's *T* score of 72 (%ile = 96) on the GEC is significantly elevated as compared to the scores of his peers, suggesting significant difficulty in one or more areas of executive function.

## **Behavioral Regulation and Metacognition Indexes**

The Behavioral Regulation Index (BRI) captures the rated child's ability to shift cognitive set and modulate emotions and behavior via appropriate inhibitory control. It is comprised of the Inhibit, the Shift, and the Emotional Control scales. Intact behavioral regulation is likely to be a precursor to appropriate metacognitive problem solving. Behavioral regulation enables the metacognitive processes to successfully guide active systematic problem solving; and more generally, behavioral regulation supports appropriate self-regulation.

The Metacognition Index (MI) reflects the rated child's ability to initiate, plan, organize, self-monitor, and sustain working memory. It can be interpreted as Sample Client's ability to cognitively self-manage tasks and to monitor his performance. The MI relates directly to a child's ability to actively problem solve in a variety of contexts. It is composed of the Initiate, Working Memory, Plan/Organize, Organization of Materials, and Monitor scales.

Examination of the indexes reveals that both the Behavioral Regulation Index ( T = 71, %ile = 94) and Metacognition Index ( T = 71, %ile = 96) are elevated. This suggests more global difficulties with self-regulation, including the fundamental ability to inhibit impulses, modulate emotions, and to flexibly problem solve. These global difficulties extend to metacognitive functions, including the ability to sustain working memory, initiate, plan, organize, and self-monitor.

## Clinical Scales

The BRIEF clinical scales measure the extent to which the respondent reports problems with different types of behavior related to the eight domains of executive functioning. The following sections describe the scores obtained on the clinical scales and the suggested interpretation for each individual clinical scale.

### Inhibit

The Inhibit scale assesses inhibitory control and impulsivity. This can be described as the ability to resist impulses and the ability to stop one's own behavior at the appropriate time. Sample Client's *T* score of 64 (%ile = 84) on this scale is within the expected range as compared to his peers. Children with similar scores on the Inhibit scale are typically able to resist impulses and consider consequences before acting, and are generally perceived as "in control" of themselves.

Item	Content	Response
9	Needs to be told "no" or "stop that"	Sometimes

42		Sometimes
43		Often
45		Often
47		Often
57		Often
58		Often
59		Sometimes
69		Often

## Shift

The Shift scale assesses the ability to move freely from one situation, activity, or aspect of a problem to another as the circumstances demand. Key aspects of shifting include the ability to (a) make transitions, (b) tolerate change, (c) problem-solve flexibly, (d) switch or alternate attention, and (e) change focus from one mindset or topic to another. Sample Client's score on the Shift scale is moderately elevated as compared to like-aged peers (  $T = 68$ , %ile = 94). This suggests that Sample Client has some difficulties with behavioral shifting, attentional shifting, and/or cognitive shifting. Difficulties with shifting often compromise the efficiency of problem-solving abilities. Caregivers often describe children who have this level of difficulty with shifting as somewhat rigid and/or inflexible. Such children often prefer consistent routines. In some cases, such children are described as being unable to drop certain topics of interest or unable to move beyond a specific disappointment or unmet need. On formal assessment, children with difficulties shifting cognitively are often observed to have difficulty changing from one task to the next or sometimes from one question to the next. They sometimes require additional explanations or demonstration to grasp the demands of a novel task when first presented. They may also "carry over" a problem-solving approach, a response style, or information from a previous task that is no longer appropriate. This tendency to carry over can be seen as perseverating on content or response style from one item to the next within a task.

Item	Content	Response

62		Sometimes

## Emotional Control

The Emotional Control scale measures the impact of executive function problems on emotional expression and assesses a child's ability to modulate or control his or her emotional responses. Sample Client's score on the Emotional Control scale is significantly elevated as compared to like-aged peers (  $T = 77$ , %ile = 96). This score suggests marked concerns with regulation or modulation of emotions. Sample Client likely overreacts to events and likely demonstrates sudden outbursts, sudden and/or frequent mood changes, and excessive periods of emotional upset. Poor emotional control is often expressed as emotional lability, sudden outbursts, or emotional explosiveness. Children with difficulties in this domain often have overblown emotional reactions to seemingly minor events. Caregivers and teachers of such children frequently describe a child who cries easily or laughs hysterically with small provocation, or a child who has temper tantrums of a frequency or severity that is not age appropriate.

Item	Content	Response

27		Often
48		Often
51		Often
64		Often
66		Often
72		Often

## Initiate

The Initiate scale reflects a child's ability to begin a task or activity and to independently generate ideas, responses, or problem-solving strategies. Sample Client's score on the Initiate scale is significantly elevated compared with like-aged peers ( $T = 72$ , %ile = 97). This suggests that Sample Client has marked difficulties beginning, starting or "getting going" on tasks, activities, and problem-solving approaches. Poor initiation typically does not reflect noncompliance or disinterest in a specific task. Children with initiation problems typically want to succeed at and complete a task but they have trouble getting started. Caregivers of such children frequently report difficulties with getting started on homework or chores along with a need for extensive prompts or cues in order to begin a task or activity. Children with initiation difficulties are at risk for being viewed as "unmotivated." In the context of psychological assessment, initiation difficulties are often demonstrated in the form of difficulty with word and design fluency tasks as well as a need for additional cues from the examiner in order to begin tasks in general. Alternatively, initiation deficits may reflect depression, and this should be examined particularly if this finding is consistent with the overall affective presentation of the child.

## Working Memory

The Working Memory scale measures “on-line representational memory;” that is, the capacity to hold information in mind for the purpose of completing a task, encoding information, or generating goals, plans, and sequential steps to achieving goals. Working memory is essential to carry out multistep activities, complete mental manipulations such as mental arithmetic, and follow complex instructions. Sample Client's score on the Working Memory scale is within the average range as compared to like-aged peers (  $T = 63$ , %ile = 88). This suggests that Sample Client is able to hold an appropriate amount of information in mind or in “active memory” for further processing, encoding, and/or mental manipulation. Sample Client's score suggests an appropriate ability to sustain working memory, and is therefore able to remain attentive and focused for appropriate lengths of time.

Item	Content	Response

32		Often
39		Sometimes
60		Often

## Plan/Organize

The Plan/Organize scale measures the child's ability to manage current and future-oriented task demands. The scale is comprised of two components: plan and organize. The plan component captures the ability to anticipate future events, to set goals, and to develop appropriate sequential steps ahead of time in order to carry out a task or activity. The organize component refers to the ability to bring order to information and to appreciate main ideas or key concepts when learning or communicating information. Sample Client's score on the Plan/Organize scale is significantly elevated as compared to like-aged peers (  $T = 72$ , %ile = 96). This suggests that Sample Client has marked difficulty with the planning and the organization of information which has a negative impact on his approach to problem solving. Planning involves developing a goal or end state and then strategically determining the most effective method or steps to attain that goal. Evaluators can observe planning when a child is given a problem requiring multiple steps (e.g., assembling a puzzle or completing a maze). Sample Client may underestimate the time required to complete tasks or the level of difficulty inherent in a task. He may often wait until the last minute to begin a long-term project or assignment for school, and he may have trouble carrying out the actions needed to reach his goals.

Organization involves the ability to organize oral and written expression as well as to understand the main points expressed in presentations or written material. Organization also has a clerical component that is demonstrated, for example, in the ability to efficiently scan a visual array or to keep track of a homework assignment. Sample Client may approach tasks in a haphazard fashion, getting caught up in the details and missing the "big picture." He may have good ideas that he fails to express on tests and written assignments. He may often feel overwhelmed by large amounts of information and may have difficulty retrieving material spontaneously or in response to open-ended questions. He may, however, exhibit better performance with recognition (multiple choice) questions.

Item	Content	Response
12	Does not bring home homework, assignment sheets, materials, etc.	Sometimes

## Organization of Materials

The Organization of Materials scale measures orderliness of work, play, and storage spaces (e.g., desks, lockers, backpacks, and bedrooms). Caregivers and teachers typically can provide an abundance of examples describing a child's ability to organize, keep track of, and/or clean up their belongings. Sample Client's score on the Organization of Materials scale is significantly elevated relative to like-aged children ( $T = 71$ , %ile = 96). Sample Client is described as having marked difficulty keeping (a) his materials and his belongings reasonably well organized, (b) having his materials readily available for projects or assignments, and (c) as having considerable difficulty finding his belongings when needed. Children who have significant difficulties in this area often do not function efficiently in school or at home because they do not have their belongings readily available for use. Pragmatically, teaching a child to organize his or her belongings can be a useful, concrete tool for teaching greater task organization.

Item	Content	Response

67		Often
68		Often
71		Never
73		Often

## Monitor

The Monitor scale assesses two types of monitoring behaviors: Task-oriented monitoring or work-checking habits and Self-monitoring or interpersonal awareness. The task monitoring portion of the scale captures whether a child assesses his or her own performance during or shortly after finishing a task to ensure accuracy or appropriate attainment of a goal. The self monitoring portion of the scale evaluates whether a child keeps track of the effect that his or her behavior has on others. Sample Client's score on the Monitor scale is moderately elevated, suggesting some difficulty with monitoring (  $T = 68$ , %ile = 93). Examination of the task-monitoring and self-monitoring clusters of individual items that comprise the Monitor scale reveals strong endorsement of both task-monitoring and self-monitoring items. Children with similar patterns tend to be less cautious in their approach to tasks or assignments and often do not notice and/or check for mistakes. They are often unaware of their own behavior and the impact this behavior has on their social interactions with others. Caregivers often describe children with task-oriented monitoring difficulties as rushing through their work, as making careless mistakes, and as failing to check their work. Clinical evaluators may observe the same types of behavior during formal assessment.

65		Often

## Additional Clinical Items

The BRIEF Parent and Teacher Forms both contain additional items of clinical interest that are not included in any of the clinical scales. Although these items are not scored and therefore do not contribute to the BRIEF scale raw scores, they were retained because of their direct relevance to functional intervention programming and their relevance to specific clinical populations (e.g., Pervasive Developmental Disorders, Traumatic Brain Injury, and Attention Deficit/Hyperactivity Disorder). Careful review of these individual items can assist the examiner in identifying and targeting areas of concern for intervention and can further reinforce interpretation of the findings from the clinical scales by providing additional evidence of difficulties in the particular domain of executive function. The item summary table below includes the item numbers, item content, and the rater's item responses, as well as the BRIEF scale to which the item was originally assigned.

## **Comparison of BRIEF Working Memory and Inhibit Scales to ADHD Groups**

The BRIEF Inhibit and Working Memory scales may be helpful in identifying children with suspected Attention-Deficit/Hyperactivity Disorder (ADHD). Theoretically, inhibitory control enables self-regulation, and working memory enables sustained attention. It is important at the outset, however, to appreciate the distinction between executive functions and the diagnosis of Attention-Deficit/Hyperactivity Disorder (ADHD): Executive functions are neuropsychological constructs whereas ADHD is a neuropsychiatric diagnosis based on a cluster of observed symptoms. Although executive functions underlie the symptoms of ADHD, executive dysfunction is not synonymous with a diagnosis of ADHD. There is general agreement that different aspects of executive dysfunction contribute to the behaviors that characterize ADHD.

The Inhibit and Working Memory scales exhibit good predictive validity and good sensitivity and specificity for detecting a likely diagnosis of Attention-Deficit/Hyperactivity Disorder (ADHD) Inattentive Type or Combined Type. In clinical samples, the Working Memory scale discriminated between children with no ADHD diagnosis (healthy controls) and those with either the Inattentive or Combined types of ADHD. The Inhibit scale further distinguished between controls and children with the Combined Type of ADHD. Please refer to pages 76 through 84 in the BRIEF Professional Manual for further detail. While the BRIEF may be a helpful and efficient tool in assessing for ADHD, it is important that all relevant data be considered in the context of clinical judgment before reaching a diagnostic decision.

In this particular profile, Teacher ratings of Sample Client's working memory (  $T = 63$ , %ile = 88) and inhibitory control (  $T = 64$ , %ile = 84) fall within normal limits. This suggests that Sample Client does not exhibit significant characteristics of executive dysfunction that are often seen in children diagnosed with ADHD.

As with any diagnostic decision, consideration of all relevant clinical assessment data is essential and clinical judgment is of paramount importance. Teacher and parent rating scales, such as the BRIEF, can add valuable information to a more comprehensive assessment for ADHD.

# **Executive System Intervention**

## **A General Framework**

Given the unique nature of the executive functions in playing a “command” role in terms of guiding and regulating thought and behavior, the approach to intervention must be considered globally. First, one must consider the end goal or outcome of “good” executive function for the child. The following executive outcomes for children are proposed:

- ◆ Demonstrating purposeful, goal-directed activity
- ◆ Displaying an active problem-solving approach
- ◆ Exerting self-control
- ◆ Demonstrating maximal independence
- ◆ Exhibiting reliable and consistent behavior and thinking
- ◆ Demonstrating positive self-efficacy
- ◆ Exhibiting an internal locus of control
